Abstract: This document describes the binary formats used by CamL¹ in its “3.11.2” version for both bytecode files and marshalled data. This document is structured in two parts: the first one exposes the format of bytecode files, and the second one exposes the format of marshalled data.

Bytecode file format

The format of bytecode files is summarized by figure 1. Unused header is commonly os-executable code that looks for `ocamlrun` executable and launch it on the file. Trailer identifies the file as a caml bytecode file by magic (“Caml1999X008”) and indicates the number of sections in the file. One should notice that datas and descriptors of sections do not need to be in the same order. All character and string values use the ISO-8859-1 encoding. The remainder of this section lists possible sections with their contents.

” **CODE** ” **section (mandatory)** contains the bytecode to be executed. Its size must be a multiple of 4, as the code is composed of 4-byte integers (in little-endian representation). These integers are either instructions bytencodes or instructions arguments. The list of intructions with related arguments is given in another document “CamL Virtual Machine – Instruction set” that can be downloaded at <http://cadmium.x9c.fr>.

” **DATA** ” **section (mandatory)** contains the global data for the program, in the format defined in the second part of this document.

” **PRIM** ” **section (mandatory)** contains a null-character-terminated list of null-character-terminated strings. Each string is the name of a primitive requested for program execution. The order of these strings defines the primitive integer identifiers: the first requested primitive is given the ” 0 ” integer identifier, the second one is given the ” 1 ” integer identifier, *etc.*

” **DLLS** ” **section** contains a null-character-terminated list of null-character-terminated strings. Each string is the name of a linked library requested for program execution.

¹The official CamL website can be reached at caml.inria.fr and contains the full development suite (compiler, tools, virtual machine, *etc.*) as well as links to third-party contributions.

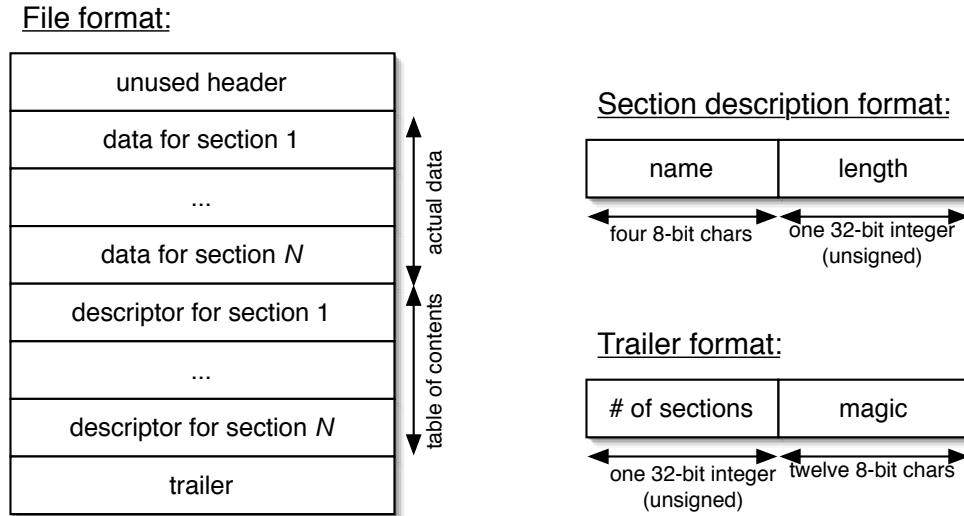

Figure 1: File format.

” DLPT ” **section** contains a null-character-terminated list of null-character-terminated strings. Each string is a path for linked library search.

” DEBUG ” **section** contains an unsigned 32-bit integer indicating the number of debug elements. Elements follow, each being a couple containing an offset (as an unsigned 32-bit integer) and a marshalled value representing an `Instruct.debug-event` instance.

Marshalled data format

The format of marshalled values is summarized by figure 2. The following paragraphs give some precisions about particular data formats.

Integer values are stored in big-endian format. They encode values of the `int` type (`int32`, `int64` and `nativeint` types are coded as custom values).

String values are stored using ISO-8859-1 encoding.

Float values are stored using IEEE 754 encoding. According to code, values may be either big-endian (`0x0B`, `0x0D`, and `0x0F` codes) or little-endian (`0x0C`, `0x0E`, and `0x07` codes).

Code offset values (`0x10`) consist in the offset of a code address, relative to code start.

Block values are serialized as shown in figure 3. For atoms, no additional data needs to be stored as the tag is given by the header. Other blocks are stored by serializing their fields in ascending order, the size (number of blocks) being given by the header. Color is used by garbage collector and is set to zero in serialized data.

	code	value	
integers	0x00	signed 8-bit integer	
	0x01	signed 16-bit integer	
	0x02	signed 32-bit integer	
	0x03	signed 64-bit integer	<i>supported only on 64-bit architectures</i>
shared elements	0x04	unsigned 8-bit offset	
	0x05	unsigned 16-bit offset	
	0x06	unsigned 32-bit offset	
blocks	0x08	32-bit header (unsigned)	block
	0x13	64-bit header (signed)	block <i>supported only on 64-bit architectures</i>
strings	0x09	unsigned 8-bit length	sequence of 8-bit characters (ISO-8859-1 encoding)
	0x0A	unsigned 32-bit length	sequence of 8-bit characters (ISO-8859-1 encoding)
floats	0x0B	64-bit float (IEEE 754 encoding)	
	0x0C	64-bit float (IEEE 754 encoding)	
	0x0D	unsigned 8-bit length	sequence of 64-bit floats (IEEE 754 encoding)
	0x0E	sequence of 64-bit floats (IEEE 754 encoding)	
	0x0F	unsigned 32-bit length	sequence of 64-bit floats (IEEE 754 encoding)
miscellaneous	0x10	unsigned 32-bit offset	16-byte checksum
	0x11	unsigned 32-bit offset	closure
	0x12	0-terminated string (8-bit ISO-8859-1 characters)	custom data

Figure 2: Data format.

32-bit header:

64-bit header:

Block content:

size = 0 → *nothing* — atom index is given by tag

Figure 3: Block values.

Custom values are stored in two parts: the first one is the custom identifier (as a null-character-terminated string, using ISO-8859-1 encoding), the second one is custom-specific data.

Shared values are references to elements already (de)serialized of the current value. The offset defines this reference, zero pointing to the last read object, one pointing to the preceding object, *etc.*

Small elements are used to shorten value representation. They are stored using the specific encoding depicted in figure 4. A code from 0x20 to 0x3F indicates a small string value, a code from 0x40 to 0x7F indicates a small `int` value, and a code from 0x80 to 0xFF indicates a small block value.

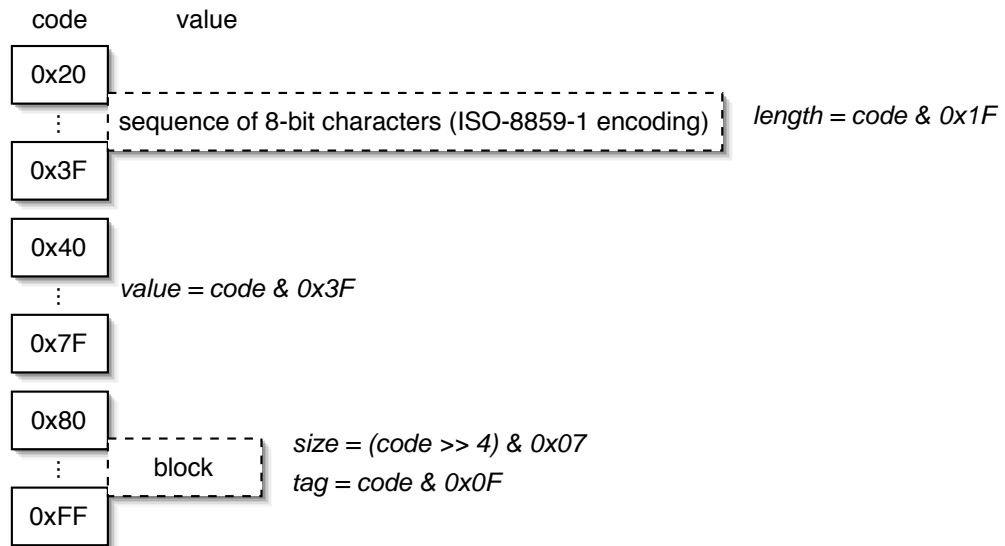

Figure 4: Small elements.
